Build a Virtual Private Cloud (VPC)

Sean Calderon

The screenshot shows the 'Create VPC' page in the AWS Management Console. The page is titled 'Create VPC' and includes a sub-header 'Resources to create'. Under 'Resources to create', there are two options: 'VPC only' (selected) and 'VPC and more'. Below this, there is a 'Name tag - optional' section with a text input field containing 'NextWork VPC'. The 'IPv4 CIDR block' section has a radio button selected for 'IPv4 CIDR manual input' and a text input field containing '10.0.0.0/16'. The 'IPv6 CIDR block' section has a radio button selected for 'No IPv6 CIDR block'. The 'Tenancy' section has a dropdown menu set to 'Default'. The 'Tags' section shows a table with two columns: 'Key' and 'Value - optional'. There is one tag with the key 'Name' and the value 'NextWork VPC'. The page footer includes the AWS logo, 'Features', and copyright information for Amazon Web Services, Inc. or its affiliates.

Introducing Today's Project!

What is Amazon VPC?

Amazon VPC is a useful for providing granularity and streamlined management of virtual networks in the cloud. It is useful in a way you create networks, segment the network with subnets and group resources according to what's the best fit for you.

How I used Amazon VPC in this project

For this project, I used Amazon VPC for creating my own virtual network in the AWS cloud, divided it in smaller segments called subnets, and attached internet gateway to a public subnet to make it accessible and reachable over the internet.

This project took me...

This project took me 15 minutes. There was no challenging part in this project because AWS has default VPCs up to subnets and internet gateways and has helped me understand it thoroughly the bits and parts of VPC.

Virtual Private Clouds (VPCs)

VPCs are division of networks or known as subnets. In networking concept, subnets divide networks in smaller parts. VPCs are the same concept but the difference it is in the cloud.

There was already a default VPC in my account ever since my AWS account was created. This is because creating resources requires no additional configuration on networking properties and is beneficial for on-demand resources.

To set up my VPC, I had to define an IPv4 CIDR block, which is my network in the vast virtual cloud of AWS. With the help of IPv4 CIDR block, resources can be assigned with IPv4 address and will be able to communicate to other resources or publicly.

Create VPC Info

A VPC is an isolated portion of the AWS Cloud populated by AWS objects, such as Amazon EC2 instances.

VPC settings Info

Resources to create Info
Create only the VPC resource or the VPC and other networking resources.

☒ VPC only ☐ VPC and more

Name tag - optional Info
Create a tag with a key of "Name" and a value that you specify.

NextWork VPC

IPv4 CIDR block Info

☒ IPv4 CIDR manual input
☐ IAM-allocated IPv4 CIDR block

IPv4 CIDR
10.0.0.0/16

CIDR block size must be between /16 and /28.

IPv6 CIDR block Info

☒ No IPv6 CIDR block
☐ IAM-allocated IPv6 CIDR block
☐ Amazon-provided IPv6 CIDR block
☐ IPv6 CIDR owned by me

Tenancy Info

Default

Tags Info
A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value. You can use tags to search and filter your resources or track your AWS costs.

| Key | Value - optional | |
|---------|------------------|---|
| Q, Name | Q, NextWork VPC | <input checked="" type="button" value="X"/> <input type="button" value="Remove tag"/> |

You can add 49 more tags.

Subnets

Subnets are division of VPC to a smaller segments of IPv4 address block. There are already subnets existing in my account, one for every availability zone in the selected region.

Once I created my subnet, I ticked "enable auto-assign public IPv4 addresses". This setting makes sure EC2 instance to be launched will automatically have public ip address assigned so that it can reach the internet or can be access over the internet

The difference between public and private subnets is public subnet is publicly viewable/accessible by anyone, while private subnet does not. For a subnet to be considered public, it has to be connected to the internet gateway.

The screenshot shows the AWS Management Console interface for editing subnet settings. The breadcrumb trail is VPC > Subnets > subnet-08becf6875c7bd619 > Edit subnet settings. The page title is 'Edit subnet settings'. The 'Subnet' section shows 'Subnet ID' as subnet-08becf6875c7bd619 and 'Name' as Public 1. The 'Auto-assign IP settings' section has a description: 'Enable AWS to automatically assign a public IPv4 or IPv6 address to a new primary network interface for an instance in this subnet.' It includes a checked checkbox for 'enable auto-assign public IPv4 address' and a disabled checkbox for 'enable auto-assign customer-owned IPv4 address'. The 'Resource-based name (RBN) settings' section has a description: 'Specify the hostname type for EC2 instances in this subnet and optional RBN DNS query settings.' It includes unchecked checkboxes for 'enable resource name DNS A record on launch' and 'enable resource name DNS AAAA record on launch'. The 'Hostname type' section has radio buttons for 'Resource name' (selected) and 'IP name'. The 'DNS64 settings' section has a description: 'Enable DNS64 to allow IPv6-only services in Amazon VPC to communicate with IPv4-only services and networks.' and an unchecked checkbox for 'enable DNS64'. At the bottom right are 'Cancel' and 'Save' buttons. The footer includes 'CloudShell', 'Feedback', '© 2025, Amazon Web Services, Inc. or its affiliates.', 'Privacy', 'Terms', and 'Cookie preferences'.

Subnet

Subnet ID: subnet-08becf6875c7bd619

Name: Public 1

Auto-assign IP settings

Enable AWS to automatically assign a public IPv4 or IPv6 address to a new primary network interface for an instance in this subnet.

☒ enable auto-assign public IPv4 address

☐ enable auto-assign customer-owned IPv4 address

Resource-based name (RBN) settings

Specify the hostname type for EC2 instances in this subnet and optional RBN DNS query settings.

☐ enable resource name DNS A record on launch

☐ enable resource name DNS AAAA record on launch

Hostname type

☒ Resource name

☐ IP name

DNS64 settings

Enable DNS64 to allow IPv6-only services in Amazon VPC to communicate with IPv4-only services and networks.

☐ enable DNS64

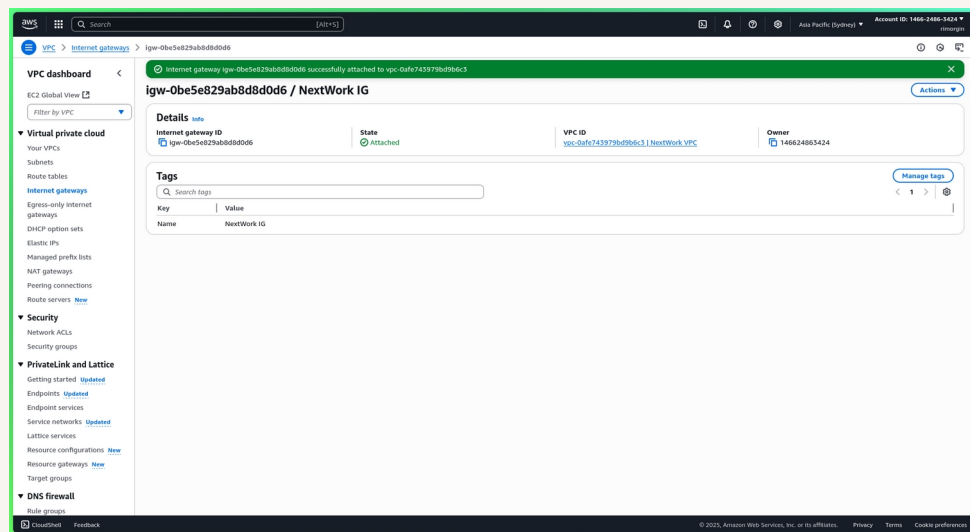

Cancel Save

Internet gateways

Internet gateways are what makes VPCs readily accessible and available over the internet so that any resources or, to be exact, EC2 instances that acts as a public-facing servers for a website, vpn, or etc.

Attaching an internet gateway to a VPC means my resources can now be accessible or reachable over the internet. If I missed this step its impossible for my resources to have access to.
